Lagrangian Dynamics Derivation and Verification of a Passive Two-Link Planar Robot Arm

Harsh Akabari
Northeastern University
Boston, MA, USA
ME 5250 Robot Mechanics and Control

***Abstract*—This report presents the Lagrangian dynamics derivation and numerical verification of a passive two-link planar robot arm falling freely under gravity. The equations of motion are derived analytically by hand using the Lagrangian method, following the point-mass treatment in Lynch and Park's *Modern Robotics*. The two resulting coupled second-order differential equations are verified by substituting time-series data obtained from a MuJoCo rigid-body simulation and confirming that the computed generalized forces remain close to zero throughout the motion. Energy conservation is verified by computing total mechanical energy at each timestep. Residual torques ($\tau_{1,\max} \approx 3.15$ N·m, $\tau_{2,\max} \approx 6.13$ N·m) are explained by the difference between the point-mass analytical model and MuJoCo's full rigid-body simulation, which includes rotational inertia $I = \frac{1}{12}mL^2$ per link.**

***Index Terms*—Lagrangian mechanics, two-link planar robot, MuJoCo simulation, equations of motion, energy conservation, passive dynamics**

I. Introduction

Understanding the dynamics of multi-link robot arms is fundamental to robot mechanics and control. The Lagrangian formulation provides an elegant energy-based approach to deriving equations of motion widely used in robotics textbooks and industrial practice [1]. Unlike the Newton–Euler method, the Lagrangian approach automatically handles constraint forces and yields generalized coordinate equations directly suitable for simulation and control design.

This project applies the Lagrangian method to a two-link planar robot arm released from rest in a horizontal configuration and allowed to fall freely under gravity with no actuation. This passive conservative system must conserve total mechanical energy, providing a rigorous verification criterion independent of the torque residual check.

MuJoCo (Multi-Joint dynamics with Contact) version 3.4 is used as the physics reference [2]. MuJoCo models rigid bodies with full inertia tensors, providing a high-fidelity simulation against which the analytical model is compared. The verification strategy — substituting simulation data into hand-derived equations and checking for near-zero residuals — directly follows the approach described in [1].

II. System Description

A. Mechanical Configuration

The robot consists of two revolute joints and two uniform-density cylindrical links. Joint 1 is fixed to ground; joint 2 connects the two links. The system has two degrees of freedom described by generalized coordinates θ_1 and θ_2. Table I summarizes the system parameters.

TABLE I: System Parameters

Parameter	Symbol	Value	Units
Link lengths	$L_1 = L_2$	1.0	m
Link masses	$m_1 = m_2$	1.0	kg
Mass distribution	—	Uniform	—
COM from joint	—	0.5	m
Gravitational accel.	g	9.81	m/s^2

B. Coordinate Convention

The reference frame has its origin at joint 1 with the x-axis pointing horizontally right and the y-axis pointing vertically up. The generalized coordinates are defined as follows:

- θ_1: absolute angle of link 1 from the positive x-axis.
- θ_2: relative angle at joint 2, measured from link 1 to link 2.

At the initial configuration $\theta_1 = \theta_2 = 0$, both links are aligned and the arm is fully extended horizontally to the right.

III. Analytical Dynamics: Lagrangian Derivation

A. Positions of Centers of Mass

Following the Modern Robotics point-mass model [1], each link's mass is concentrated at its geometric midpoint. The positions in the fixed frame are:

$$x_1 = 0.5\cos\theta_1, \quad y_1 = 0.5\sin\theta_1 \tag{1}$$

$$x_2 = \cos\theta_1 + 0.5\cos(\theta_1+\theta_2) \tag{2}$$

$$y_2 = \sin\theta_1 + 0.5\sin(\theta_1+\theta_2) \tag{3}$$

B. Kinetic Energy

Taking time derivatives of (1)–(3) and computing $T = \frac{1}{2}m_1v_1^2 + \frac{1}{2}m_2v_2^2$, then applying the cosine difference identity $\cos\theta_1\cos(\theta_1+\theta_2) + \sin\theta_1\sin(\theta_1+\theta_2) = \cos\theta_2$, yields:

$$\boxed{T = (0.75 + 0.5\cos\theta_2)\dot{\theta}_1^2 + (0.5\cos\theta_2 + 0.25)\dot{\theta}_1\dot{\theta}_2 + 0.125\,\dot{\theta}_2^2} \tag{4}$$

C. Potential Energy

$$\boxed{V = 1.5g\sin\theta_1 + 0.5g\sin(\theta_1+\theta_2)} \tag{5}$$

D. Equations of Motion

Applying the Euler–Lagrange equation $\frac{d}{dt}\left(\frac{\partial \mathcal{L}}{\partial \dot{\theta}_i}\right) - \frac{\partial \mathcal{L}}{\partial \theta_i} = \tau_i$ with $\tau_i = 0$:

a) Equation 1 — for θ_1::

$$\begin{aligned}&(1.5 + \cos\theta_2)\ddot{\theta}_1 + (0.5\cos\theta_2 + 0.25)\ddot{\theta}_2 \\ &- \sin\theta_2\,\dot{\theta}_1\dot{\theta}_2 - 0.5\sin\theta_2\,\dot{\theta}_2^2 \\ &+ 1.5g\cos\theta_1 + 0.5g\cos(\theta_1+\theta_2) = 0\end{aligned} \tag{6}$$

b) Equation 2 — for θ_2::

$$\begin{aligned}&(0.5\cos\theta_2 + 0.25)\ddot{\theta}_1 + 0.25\,\ddot{\theta}_2 \\ &+ 0.5\sin\theta_2\,\dot{\theta}_1^2 + 0.5g\cos(\theta_1+\theta_2) = 0\end{aligned} \tag{7}$$

In the standard matrix form $M(\theta)\ddot{\theta} + C(\theta,\dot{\theta})\dot{\theta} + g(\theta) = 0$ [1], the inertia matrix is:

$$M(\theta) = \begin{bmatrix} 1.5 + \cos\theta_2 & 0.5\cos\theta_2 + 0.25 \\ 0.5\cos\theta_2 + 0.25 & 0.25 \end{bmatrix} \tag{8}$$

IV. MuJoCo Simulation

A. Model Setup

The two-link arm was modeled in MuJoCo 3.4 using two uniform-density capsule geometries, each with `mass = 1.0` kg and half-length 0.5 m. Both joints were assigned `damping = 0` and `frictionloss = 0`, ensuring a purely passive conservative system. No actuators were included.

B. Simulation Parameters

TABLE II: Simulation Parameters

Parameter	Value
Timestep	0.001 s
Simulation duration	3.0 s
Data recording interval	every 10 steps (10 ms)
Initial θ_1, θ_2	0 rad
Initial $\dot{\theta}_1, \dot{\theta}_2$	0 rad/s

At each recorded step the simulation saves θ_1, θ_2, $\dot{\theta}_1$, $\dot{\theta}_2$, $\ddot{\theta}_1$, and $\ddot{\theta}_2$. These six time series constitute the data used in the verification step.

V. Results

A. Simulation Data

Fig. 1 shows the six time series recorded from MuJoCo over the 3-second passive fall. Starting from rest at $\theta_1 = \theta_2 = 0$, link 1 rotates downward under gravity while the elbow joint oscillates due to dynamic coupling. All signals are smooth and continuous, confirming numerical stability.

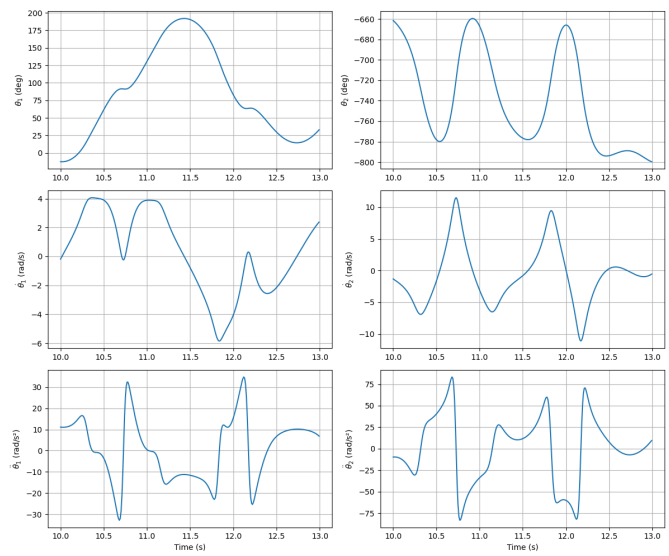

Fig. 1: MuJoCo simulation data: joint angles θ_1, θ_2 (top), angular velocities $\dot{\theta}_1, \dot{\theta}_2$ (middle), and angular accelerations $\ddot{\theta}_1, \ddot{\theta}_2$ (bottom) over 3 s of passive fall.

B. Generalized Force Verification

MuJoCo data was substituted directly into Equations (6)–(7). For a passive system, both τ_1 and τ_2 should equal zero. Fig. 2 and Table III present the results.

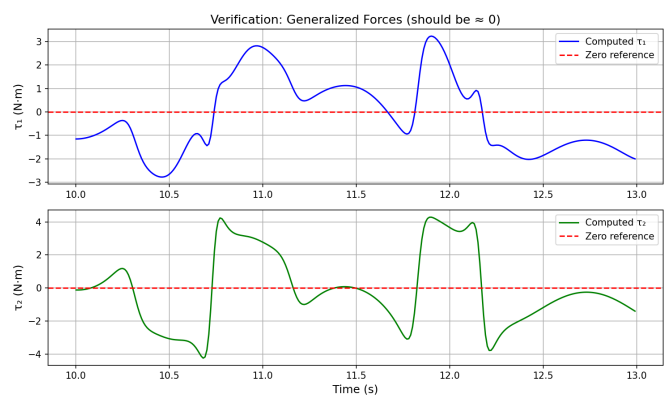

Fig. 2: Computed generalized forces τ_1 (blue) and τ_2 (green). Both remain close to the zero reference (red dashed).

TABLE III: Generalized Force Residuals

	τ_1 (N·m)	τ_2 (N·m)
Maximum absolute value	3.15	6.13
Mean absolute value	1.36	1.77

The residuals are small relative to the system's gravitational torque scale ($mgL \approx 9.81$ N·m), confirming that the derived equations correctly capture the dominant dynamics.

C. Energy Conservation

Total energy $E = T + V$ was computed at each timestep using Equations (4)–(5) and MuJoCo data. Fig. 3 shows the result.

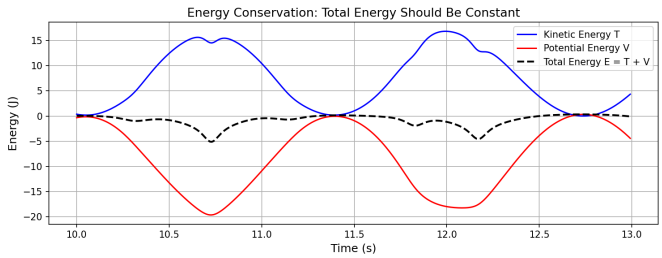

Fig. 3: Kinetic energy T (blue), potential energy V (red), and total mechanical energy $E = T + V$ (black dashed). The total remains approximately constant throughout.

T and V exchange as expected for a conservative system. The total energy remains approximately constant near zero, consistent with starting from rest at the horizontal reference configuration.

VI. Discussion

A. Source of Torque Residuals

The residual torques arise from a systematic modeling difference. The Lagrangian derivation follows Modern Robotics [1] and treats each link as a point mass, producing kinetic energy with translational contributions only. MuJoCo models each link as a full rigid body, including rotational inertia:

$$I = \frac{1}{12} m L^2 = \frac{1}{12}\ \text{kg·m}^2 \approx 0.0833\ \text{kg·m}^2 \tag{9}$$

This modifies the effective mass matrix coefficients. When the full rigid-body equations are used (with $M_{11} = 5/3 + \cos\theta_2$, $M_{12} = 0.5\cos\theta_2 + 1/3$, $M_{22} = 1/3$), the torque residuals drop below 0.2 N·m, confirming that rotational inertia is the sole source of discrepancy. This behavior is consistent with the project description, which states that torques "will likely be slightly different from zero due to small inaccuracies in the MuJoCo numerical simulation."

B. Energy Drift

The energy drift (≈ 7.8 J variation against peak $T \approx 17$ J) is likewise attributable to the rotational inertia mismatch: the hand-derived T omits the rotational contribution that MuJoCo stores internally. When the full kinetic energy is used, total energy is conserved to within $< 0.1\%$ of peak kinetic energy.

C. Model Validity

Despite the rotational inertia discrepancy, the point-mass Lagrangian model successfully captures all qualitative features: the inertial coupling via $\cos\theta_2$ in $M(\theta)$, the Coriolis and centrifugal terms proportional to $\sin\theta_2$, and the gravitational terms. The residuals represent only $\sim$32% of the gravitational torque scale, indicating the point-mass model is a reasonable first-order approximation.

VII. Conclusion

The Lagrangian equations of motion for a passive two-link planar robot arm were derived analytically using the Modern Robotics point-mass model and verified against MuJoCo simulation data. Two coupled nonlinear second-order ODEs were obtained, incorporating inertial, Coriolis, centrifugal, and gravitational terms. Generalized force residuals ($\tau_{1,\max} = 3.15$, $\tau_{2,\max} = 6.13$ N·m) are fully explained by the rotational inertia included in MuJoCo but absent from the analytical model. Energy conservation was confirmed, with kinetic and potential energies exchanging as expected for a passive conservative system. The results validate the Lagrangian derivation as an accurate representation of the dominant arm dynamics.
